Creating Pulse Generator with Controlled Duration

PLC programming for multiple pulses per trigger

This describes one method of generating multi-shot triggers in the GP/GD series cameras by using enable duration control.

By using the internal PLC functions, you can generate multiple pulses and the output is limited to only the enable period. If camera is set to async reset mode (0x00 23 00 00 00 01), it can generate a number of images which are programmed with the multi-shot generator.

Step 1

Make PLC LUT to select enable control. This can be external TTL (TTL Input 0) or GPIO Control Bit (0). In Signal routing Block and Lookup Table, set I0 with TTL Input 0 (default) or GPIO Control Bit 0.

| E Progr | ammable Logic Controller | | |
|-----------------------------|-----------------------------------|--|--|
| 🗉 Sign | al Routing Block and Lookup Table | | |
| IO | IO GPIO Control Bit 0 | | |
| I1 | TTL Input 1 | | |
| 12 | LVDS Input | | |
| I3 | Optically-Isolated Input | | |
| I4 | GPIO Control Bit 1 | | |
| 15 | IS GPIO Control Bit 0 | | |
| I6 Pulse Generator 1 Output | | | |
| 17 | Pulse Generator 0 Output | | |
| | | | |

The other inputs are set to the default values since the default settings are appropriate for this application.

Step 2

Configure the pulse generator to create a 10ms pulse per trigger. The first pulse is needed immediately after the trigger. The delay is the minimum and the width is set for 10ms.

| ngine Port Communicatio | | | |
|---|--------------------------------|--|--|
| 1 | | | |
| I5 | GPIO Control Bit 0 | | |
| I6 | Pulse Generator 1 Output | | |
| I7 Pulse Generator 0 Output | | | |
| Lookup Table | Q0 = 10 & 17 Q1 = 11 | | |
| Cohonood Eurotic | Plack | | |
| Enhanced Functio | | | |
| Enhanced Function Pulse Generator Width (high) | | | |
| 🗉 Pulse Generato | or O | | |
| □ Pulse Generato Width (high) | or 0 1000 | | |
| □ Pulse Generato Width (high) Delay (low) | or 0 1000 10 | | |
| Pulse Generato Width (high) Delay (low) Granularit | or 0 1000 10 333 🗹 | | |

Set the granularity = 333, then each count is 10μ s.. Therefore, 10ms width is 1,000.

For this simple example, we set the pulse generator to periodic (continuous) mode. Mark "Emit periodic ...".

Step 3

The LUT now needed to be set up.

The inputs to the trigger are coming from pulse generator_0 output and the trigger.

Q0 = 10 & 17

This logic generates a trigger which is enabled when I0 is active high. Q1 is an output to monitor functions. I1 is default strobe output (exposure signal).

Optional LUT programming

Configuration - Advanced

1

Asynchronous trigger with Enable edge:

If pulse generator is required to reset at enable edge, we cannot use the periodic mode of pulse generator but instead use a rising edge trigger. To make feed back to repeat multiple pulses, the LUT is programmed to create the feedback from the Pulse generator output to input. Q9 (input to pulse generator 0) is connected to the enable pulse and its own inverted output.

In this example, the enable pulse is active low (pulses are output when I0 is low).

| Programmable L | ogic Controller | | |
|--------------------|---|--|--|
| 🗉 Signal Routing B | lock and Lookup Table | | |
| IO | GPIO Control Bit 0 | | |

Creating Pulse Generator with Controlled Duration

Pulse Generator Control from Coyote:

Normal programming is shown in Enhanced Function Block.

| Flow Control | | | |
|-------------------|--------------------------|---|--|
| 🗉 Programmable L | ogic Controller | | |
| | ock and Lookup Table | | |
| 🗉 Enhanced Functi | on Block | | |
| 🗉 Pulse Generat | or 0 | | |
| Width (high) | Width (high) 1000 | | |
| Delay (low) | 10 | | |
| Granularit | 333 | | |
| Emit perio | | | |
| Trigger mode | Triggered on rising edge | ~ | |
| Pulse peri | 10130220 | | |
| Pulse freq | 98.714539 | | |
| 🗉 Pulse Generat | or 1 | | |
| 🗉 Pulse Generat | or 2 | | |
| | | | |

In the Coyote application, you can use another method in IPEngine tab.

| Pulse Generators | | | | | |
|-----------------------|--------------------|------|---|------------|----|
| Controls Selection | Pulse Generator #0 | | | | |
| Delay (low duration) | 0 | 10 | * | 100,200 | ns |
| Width (high duration) | 0 | 1000 | * | 10,020,000 | ns |
| Granularity | 0 | 333 | * | 10,020 | ns |
| Periodic | | | | | |

In this application, the frame rate is controlled with three parameters. For the simplest case, you can choose Width variation as the variables. Since the Granularity is fixed at 10 μ s, any multiple of Width dictates the frame rate. In the example, 1000 represent 10ms period of frame rate = 100 fps. If 25 fps is required, set the Width to 4000 (=40ms = 25fps).

GPIO Control Bit:

In IP Engine tab, the Control Bit is used.

By marking Set value, the GPIO Control goes to high. By demarking, it goes to low. In this application, pulses are output during high and disabled during low.

| PLC Control | Bits | | | |
|--------------------------------------|-----------|-----------------|--|--|
| PLC Control Bit status | | | | |
| | Set value | IP Engine value | | |
| PLC_CTRL0 | | | | |
| PLC_CTRL1 | | | | |
| PLC_CTRL2 | | | | |
| PLC_CTRL3 | | | | |
| Broadcast requests to all IP Engines | | | | |
